# DIME TIME

## PATENT OVERVIEW

Investor summary of the Dime Time provisional patent.

**Tim Carlisle · Founder & CEO**

dime-time.com · tim@dime-time.com

01

THE INVENTION

# Dual-Split, Multi-Destination Round-Up System

USPTO provisional patent — drafted and ready for filing.

### WHAT IT IS

A financial automation engine that splits transaction round-ups across multiple destinations.

### WHO IT'S FOR

Consumers carrying debt who also want to build long-term assets — without changing behavior.

### WHY IT MATTERS

First system to convert everyday spending into simultaneous debt reduction and asset acquisition.

02

THE PROBLEM

# Consumers Are Forced to Choose

Existing tools handle one financial goal at a time. Real life isn't that simple.

**TODAY**

- Round-up apps send change to one place — savings or stocks.
- Debt apps focus only on payoff — assets are ignored.
- Crypto apps ignore the debt sitting on the credit card.
- Users must pick one — and usually pick neither.

**WHAT'S MISSING**

- A single engine that splits round-ups across destinations.
- User-controlled allocation across debt AND assets.
- Real-time orchestration with idempotent execution.
- A reconciliation ledger tracking every micro-transfer.

03

THE BREAKTHROUGH

# One Engine. Two Goals. Every Transaction.

The patent covers a system that turns spare change into simultaneous debt reduction and asset growth.

A computerized microallocation system that detects user transactions, calculates round-up amounts,
applies a user-controlled allocation vector, and routes the resulting funds across multiple
financial destinations — including debt repayment and digital asset acquisition — in real time.

# From Coffee to Capital in Four Steps

The engine runs passively in the background — no behavior change required.

1. **Transaction Detected**
   Plaid streams every purchase as it posts.
2. **Round-Up Calculated**
   Engine computes delta to next whole dollar.
3. **Allocation Applied**
   User's vector splits the round-up — e.g., 80/20.
4. **Routed to Destinations**
   ACH to debt, Coinbase to crypto. Logged in ledger.

**Idempotent orchestration — no duplicate executions, no missed transfers.**

05

SYSTEM ARCHITECTURE

# The End-to-End Allocation Pipeline

Mobile app → backend engines → external rails. Every layer is patent-claimed.

**MOBILE APP**

User interface, allocation slider, dashboard

**INGESTION ENGINE**

Plaid webhooks + transaction normalization

**ROUND-UP CALCULATOR**

Delta-to-next-dollar computation

**ALLOCATION ENGINE**

Vector applied to round-up — split into N portions

**ROUTING + ORCHESTRATION**

ACH, Mercury, Coinbase — idempotent execution

**RECONCILIATION LEDGER**

Every state, every transfer, fully tracked

**EXTERNAL INTEGRATIONS**

Plaid · Mercury · Coinbase · ACH network · Loan servicers · Card issuers

06

WORKED EXAMPLE

# A $4.35 Coffee Becomes Two Investments

Every transaction triggers a split. Below: a single round-up at an 80/20 vector.

TRANSACTION

**$4.35**

ROUND-UP ($5.00 − $4.35)

**$0.65**

DEBT · 80%

**$0.52**

ACH → credit card

BITCOIN · 20%

**$0.13**

Coinbase market buy

# Debt and Bitcoin — From the Same Round-Up

The core embodiment: one allocation vector, two simultaneous outcomes.

**ROUND-UP POOL**

Allocation Vector V = [D, A]

**DEBT REPAYMENT RAIL**

Idempotent · reconciled · retried on failure

Credit card / Loan servicer

**DIGITAL ASSET RAIL**

Idempotent · reconciled · retried on failure

Coinbase / Custodial wallet

# The Vector Extends to Any Number of Destinations

$V = [w_1, w_2, w_3, \ldots w_n]$ — $\Sigma w_n = 100\%$. Future destinations are protected by claim.

**ALLOCATION VECTOR V = [50% debt, 20% Bitcoin, 20% savings, 10% charity]**

| CREDIT CARD | BITCOIN | SAVINGS | INVESTMENT | DESTINATION N |
|---|---|---|---|---|
| Highest-interest debt | Long-term store of value | Emergency reserve | Brokerage / index funds | Future: yield, charity, refinance |

**The patent claims cover the N-dimensional model — not just two destinations.**

09

USER CONTROL

# One Slider. Total Control.

Continuous 0–100% allocation. The user picks the mix. The engine handles the rest.

Debt 100% — Bitcoin 0%

Debt 80% — Bitcoin 20%

Debt 50% — Bitcoin 50%

Debt 0% — Bitcoin 100%

**Allocation vector is stored, versioned, and applied to every future round-up.**

10

WHAT'S PROTECTED

# Five Claims That Build the Moat

Plain-English summary of the strongest claims in the provisional filing.

| | | |
|---|---|---|
| 01 | DUAL-SPLIT ROUND-UPS | Splitting a single round-up across debt repayment AND digital asset acquisition — in one transaction. |
| 02 | CONTINUOUS 0-100% VECTOR | Any user-selectable ratio across the full 0–100% range, including fractional values. |
| 03 | N-DESTINATION EXTENSION | Beyond two — credit cards, loans, savings, investments, crypto, charity, or any future endpoint. |
| 04 | DYNAMIC ADJUSTMENT | Allocation that adapts to APR, balances, market conditions, cash flow, or risk preference. |
| 05 | IDEMPOTENT EXECUTION + LEDGER | No duplicate transfers. Every state — created → settled → reconciled — is tracked end-to-end. |

WHY IT MATTERS

# Defensible. Extensible. Licensable.

The patent isn't just protection — it's a platform for everything Dime Time builds next.

### DEFENSIBILITY

First-to-file on the dual-split round-up engine. Replicating requires re-engineering core IP plus 6–12 months of integration work.

### LICENSING POTENTIAL

Any neobank, lender, or crypto app could license the allocation engine via API to add Dime Time-style functionality.

### EXTENSIBILITY

Forward-claimed: AI-driven allocation optimization, yield destinations, refinancing tools, and credit optimization.
